

# Info zu *SimplexNumerica* V17

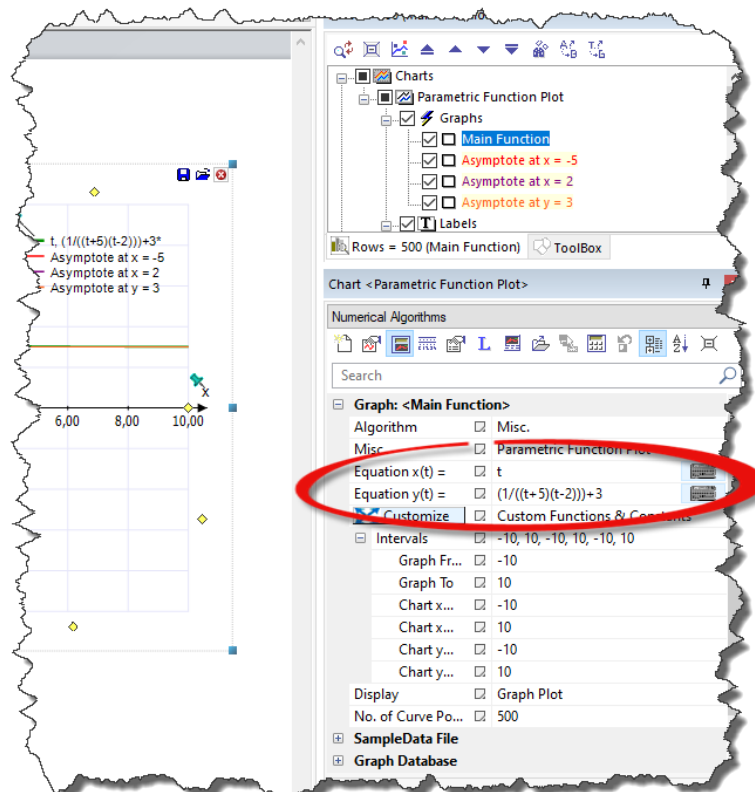

## List of Formula Parser Functions

Explicitly entered formulas are required at various points in the program. Here is the best-known example: The function plot. Available in the algorithm ribbon bar, icon Function plot.

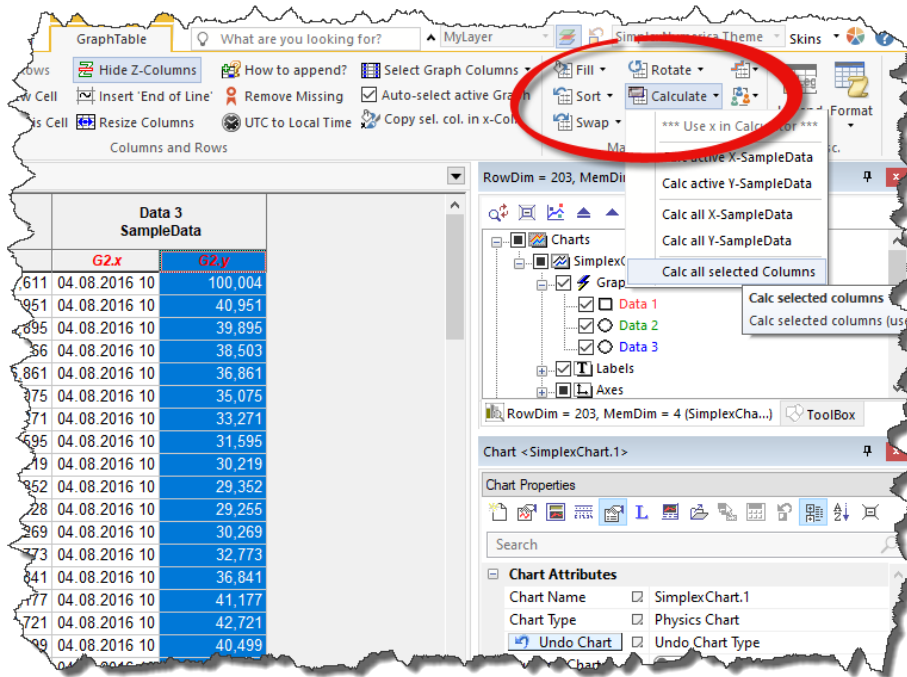

The formula can be entered directly via the properties or by means of *Simplexety*.

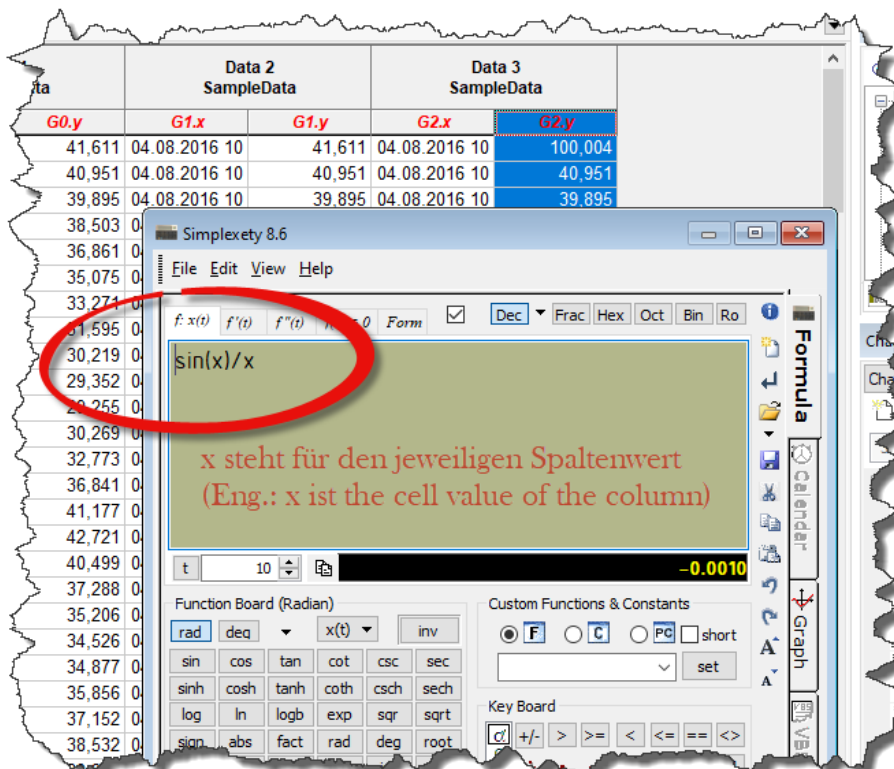

Another place where you need a formula is the GraphTable.

# Label Format

Here, for example, you want to correct the data of certain columns with a formula.

Press the Button

to quit the dialog.

# Label Format

---

Here is a list of Formula Parser Functions adapted from the famous program Graph by Ivan Johansen (SimplexNumerica's author Ralf Wirtz got a special license from Mr. Johansen).

The following is a list of all variables, constants, operators and functions supported by the program. The list of operators shows the operators with the highest precedence first. The precedence of operators can be changed through the use of brackets. (), {}, and [] may all be used alike. Notice that expressions in *SimplexNumerica* are case insensitive, i.e. there are no difference between upper- and lower-case characters. The only exception is e as Euler's constant and E as the exponent in a number in scientific notation.

The following table shows all inbuilt **Constants**:

Constant	Description
x	The independent variable used in standard functions.
t	The independent variable called parameter for parametric functions and polar angle for polar functions.
e	Euler's constant. In this program defined as $e=2.718281828459045235360287$
pi	The constant p, which in this program is defined as $pi=3.141592653589793238462643$
undef	Always returns an error. Used to indicate that part of a function is undefined.
i	The imaginary unit. Defined as $i^2 = -1$ . Only useful when working with complex numbers.
inf	The constant for infinity. Only useful as argument to the integrate function.
rand	Evaluates to a random number between 0 and 1.

The next table shows all inbuilt **Operator**:

Operator	
Exponentiation (^)	Raise to the power of an exponent. Example: $f(x)=2^x$
Negation (-)	The negative value of a factor. Example: $f(x)=-x$
Logical NOT (not)	not a evaluates to 1 if a is zero, and evaluates to 0 otherwise.
Multiplication (*)	Multiplies two factors. Example: $f(x)=2*x$
Division (/)	Divides two factors. Example: $f(x)=2/x$
Addition (+)	Adds two terms. Example: $f(x)=2+x$
Subtraction (-)	Subtracts two terms. Example: $f(x)=2-x$

# Label Format

---

Greater than (>)	Indicates if an expression is greater than another expression.
Greater than or equal to (>=)	Indicates if an expression is greater or equal to another expression.
Less than (<)	Indicates if an expression is less than another expression.
Less than or equal to (<=)	Indicates if an expression is less or equal to another expression.
Equal (=)	Indicates if two expressions evaluate to the exact same value.
Not equal (<>)	Indicates if two expressions does not evaluate to the exact same value.
Logical AND (and)	a and b evaluates to 1 if both a and b are non-zero, and evaluates to 0 otherwise.
Logical OR (or)	a or b evaluates to 1 if either a or b are non-zero, and evaluates to 0 otherwise.
Logical XOR (xor)	a xor b evaluates to 1 if either a or b, but not both, are non-zero, and evaluates to 0 otherwise.

The next table shows all inbuilt **Functions**:

Function	Description
<b>Trigometric</b>	
sin	Returns the sine of the argument, which may be in radians or degrees.
cos	Returns the cosine of the argument, which may be in radians or degrees.
tan	Returns the tangent of the argument, which may be in radians or degrees.
asin	Returns the inverse sine of the argument. The returned value may be in radians or degrees.
acos	Returns the inverse cosine of the argument. The returned value may be in radians or degrees.
atan	Returns the inverse tangent of the argument. The returned value may be in radians or degrees.
sec	Returns the secant of the argument, which may be in radians or degrees.
csc	Returns the cosecant of the argument, which may be in radians or degrees.
cot	Returns the cotangent of the argument, which may be in radians or degrees.
asec	Returns the inverse secant of the argument. The returned value may be in radians or degrees.
acsc	Returns the inverse cosecant of the argument. The returned value may be in radians or degrees.
acot	Returns the inverse cotangent of the argument. The returned value may be in radians or degrees.

# Label Format

---

	<b>Hyperbolic</b>
sinh	Returns the hyperbolic sine of the argument.
cosh	Returns the hyperbolic cosine of the argument.
tanh	Returns the hyperbolic tangent of the argument.
asinh	Returns the inverse hyperbolic sine of the argument.
acosh	Returns the inverse hyperbolic cosine of the argument.
atanh	Returns the inverse hyperbolic tangent of the argument.
csch	Returns the hyperbolic cosecant of the argument.
sech	Returns the hyperbolic secant of the argument.
coth	Returns the hyperbolic cotangent of the argument.
acsch	Returns the inverse hyperbolic cosecant of the argument.
asech	Returns the inverse hyperbolic secant of the argument.
acoth	Returns the inverse hyperbolic cotangent of the argument.
	<b>Power and Logarithm</b>
sqr	Returns the square of the argument, i.e. the power of two.
exp	Returns e raised to the power of the argument.
sqrt	Returns the square root of the argument.
root	Returns the nth root of the argument.
ln	Returns the logarithm with base e to the argument.
log	Returns the logarithm with base 10 to the argument.
logb	Returns the logarithm with base n to the argument.
	<b>Complex</b>
abs	Returns the absolute value of the argument.
arg	Returns the angle of the argument in radians or degrees.
conj	Returns the conjugate of the argument.
re	Returns the real part of the argument.

# Label Format

---

im	Returns the imaginary part of the argument.
	<b>Rounding</b>
trunc	Returns the integer part of the argument.
fract	Returns the fractional part of the argument.
ceil	Rounds the argument up to nearest integer.
floor	Rounds the argument down to the nearest integer.
round	Rounds the first argument to the number of decimals given by the second argument.
	<b>Piecewise</b>
sign	Returns the sign of the argument: 1 if the argument is greater than 0, and -1 if the argument is less than 0.
u	Unit step: Returns 1 if the argument is greater than or equal 0, and 0 otherwise.
min	Returns the smallest of the arguments.
max	Returns the greatest of the arguments.
range	Returns the second argument if it is in the range of the first and third argument.
if	Returns the second argument if the first argument does not evaluate to 0; Else the third argument is returned.
	<b>Special</b>
integrate	Returns the numeric integral of the first argument from the second argument to the third argument.
sum	Returns the sum of the first argument evaluated for each integer in the range from the second to the third argument.
product	Returns the product of the first argument evaluated for each integer in the range from the second to the third argument.
fact	Returns the factorial of the argument.
gamma	Returns the Euler gamma function of the argument.
beta	Returns the beta function evaluated for the arguments.
W	Returns the Lambert W-function evaluated for the argument.

# Label Format

---

zeta	Returns the Riemann Zeta function evaluated for the argument.
mod	Returns the remainder of the first argument divided by the second argument.
dnorm	Returns the normal distribution of the first argument with optional mean value and standard deviation.

Notice the following relations:

$$\sin(x)^2 = (\sin(x))^2$$

$$\sin 2x = \sin(2x)$$

$$\sin 2+x = \sin(2)+x$$

$$\sin x^2 = \sin(x^2)$$

$$2(x+3)x = 2*(x+3)*x$$

$$-x^2 = -(x^2)$$

$$2x = 2*x$$

$$e^{2x} = e^{(2*x)}$$

$$x^{2^3} = x^{(2^3)}$$

---

## Constants

### rand constant

Returns a random number in the range 0 to 1.

Syntax

rand

Description

rand is used as a constant but returns a new pseudo-random number each time it is evaluated. The value is a real number in the range [0;1].

Remarks

Because rand returns a new value each time it is evaluated, a graph using rand will not look the same each time it is drawn. A graph using rand will also change when the program is forced to redraw, e.g. because the coordinate system is moved, resized or zoomed.

Implementation

rand uses a multiplicative congruential random number generator with period  $2^{32}$  to return successive pseudo-random numbers in the range from 0 to 1.

# Label Format

---

## **Trigonometric**

### **sin function**

Returns the sine of the argument.

Syntax

$\sin(z)$

Description

The sin function calculates the sine of an angle  $z$ , which may be in radians or degrees depending on the current settings.  $z$  may be any numeric expression that evaluates to a real number or a complex number. If  $z$  is a real number, the result will be in the range -1 to 1.

Remarks

For arguments with a large magnitude, the function will begin to lose precision.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Trigonometric\\_functions#Sine](http://en.wikipedia.org/wiki/Trigonometric_functions#Sine)]

---

### **cos function**

Returns the cosine of the argument.

Syntax

$\cos(z)$

Description

The cos function calculates the cosine of an angle  $z$ , which may be in radians or degrees depending on the current settings.  $z$  may be any numeric expression that evaluates to a real number or a complex number. If  $z$  is a real number, the result will be in the range -1 to 1.

Remarks

For arguments with a large magnitude, the function will begin to lose precision.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Trigonometric\\_functions#Cosine](http://en.wikipedia.org/wiki/Trigonometric_functions#Cosine)]

---

# Label Format

---

## tan function

Returns the tangent of the argument.

Syntax

`tan(z)`

Description

The tan function calculates the tangent of an angle  $z$ , which may be in radians or degrees depending on the current settings.  $z$  may be any numeric expression that evaluates to a real number or a complex number.

Remarks

For arguments with a large magnitude, the function will begin to lose precision. tan is undefined at  $z = p\pi/2$ , where  $p$  is an integer, but the function returns a very large number if  $z$  is near the undefined value.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Trigonometric\\_functions#Tangent](http://en.wikipedia.org/wiki/Trigonometric_functions#Tangent)]

---

## asin function

Returns the inverse sine of the argument.

Syntax

`asin(z)`

Description

The asin function calculates the inverse sine of  $z$ . The result may be in radians or degrees depending on the current settings.  $z$  may be any numeric expression that evaluates to a real number. This is the reverse of the sin function.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Inverse\\_trigonometric\\_functions](http://en.wikipedia.org/wiki/Inverse_trigonometric_functions)]

---

## acos function

Returns the inverse cosine of the argument.

Syntax

`acos(z)`

Description

The acos function calculates the inverse cosine of  $z$ . The result may be in radians or degrees depending on the current settings.  $z$  may be any numeric expression that evaluates to a real number. This is the reverse of the cos function.

# Label Format

---

See also

Wikipedia [[http://en.wikipedia.org/wiki/Inverse\\_trigonometric\\_functions](http://en.wikipedia.org/wiki/Inverse_trigonometric_functions)]

---

## atan function

Returns the inverse tangent of the argument.

Syntax

atan(z)

Description

The atan function calculates the inverse tangent of  $z$ . The result may be in radians or degrees depending on the current settings.  $z$  may be any numeric expression that evaluates to a real number. This is the reverse of the tan function.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Inverse\\_trigonometric\\_functions](http://en.wikipedia.org/wiki/Inverse_trigonometric_functions)]

---

## sec function

Returns the secant of the argument.

Syntax

sec(z)

Description

The sec function calculates the secant of an angle  $z$ , which may be in radians or degrees depending on the current settings.  $\sec(z)$  is the same as  $1/\cos(z)$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number.

Remarks

For arguments with a large magnitude, the function will begin to lose precision.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Trigonometric\\_functions#Reciprocal\\_functions](http://en.wikipedia.org/wiki/Trigonometric_functions#Reciprocal_functions)]

---

## csc function

Returns the cosecant of the argument.

Syntax

csc(z)

Description

The csc function calculates the cosecant of an angle  $z$ , which may be in radians or degrees depending on

# Label Format

---

the current settings.  $\csc(z)$  is the same as  $1/\sin(z)$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number.

## Remarks

For arguments with a large magnitude, the function will begin to lose precision.

## See also

Wikipedia [[http://en.wikipedia.org/wiki/Trigonometric\\_functions#Reciprocal\\_functions](http://en.wikipedia.org/wiki/Trigonometric_functions#Reciprocal_functions)]

---

## **cot function**

Returns the cotangent of the argument.

## Syntax

$\cot(z)$

## Description

The cot function calculates the cotangent of an angle  $z$ , which may be in radians or degrees depending on the current settings.  $\cot(z)$  is the same as  $1/\tan(z)$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number.

## Remarks

For arguments with a large magnitude, the function will begin to lose precision.

## See also

Wikipedia [[http://en.wikipedia.org/wiki/Trigonometric\\_functions#Reciprocal\\_functions](http://en.wikipedia.org/wiki/Trigonometric_functions#Reciprocal_functions)]

---

## **asec function**

Returns the inverse secant of the argument.

## Syntax

$\operatorname{asec}(z)$

## Description

The asec function calculates the inverse secant of  $z$ . The result may be in radians or degrees depending on the current settings.  $\operatorname{asec}(z)$  is the same as  $\operatorname{acos}(1/z)$ .  $z$  may be any numeric expression that evaluates to a real number. This is the reverse of the sec function.

## See also

Wikipedia [[http://en.wikipedia.org/wiki/Inverse\\_trigonometric\\_functions](http://en.wikipedia.org/wiki/Inverse_trigonometric_functions)]

---

# Label Format

---

## acsc function

Returns the inverse cosecant of the argument.

Syntax

acsc(z)

Description

The acsc function calculates the inverse cosecant of  $z$ . The result may be in radians or degrees depending on the current settings.  $\text{acsc}(z)$  is the same as  $\text{asin}(1/z)$ .  $z$  may be any numeric expression that evaluates to a real number. This is the reverse of the csc function.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Inverse\\_trigonometric\\_functions](http://en.wikipedia.org/wiki/Inverse_trigonometric_functions)]

---

## acot function

Returns the inverse cotangent of the argument.

Syntax

acot(z)

Description

The acot function calculates the inverse cotangent of  $z$ . The result may be in radians or degrees depending on the current settings.  $\text{acot}(z)$  is the same as  $\text{atan}(1/z)$ .  $z$  may be any numeric expression that evaluates to a real number. This is the reverse of the cot function.

Remarks

The acot function returns a value in the range  $]-p/2;p/2]$  ( $]-90;90]$  when calculating in degrees), which is the most common definition, though some may define it to be in the range  $]0;p[$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Inverse\\_trigonometric\\_functions](http://en.wikipedia.org/wiki/Inverse_trigonometric_functions)]

---

## **Hyperbolic**

### sinh function

Returns the hyperbolic sine of the argument.

Syntax

sinh(z)

Description

The sinh function calculates the hyperbolic sine of  $z$ .  $z$  may be any numeric expression that evaluates to a

# Label Format

---

real number or a complex number.

Hyperbolic sine is defined as:  $\sinh(z) = \frac{1}{2}(e^z - e^{-z})$

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## **cosh function**

Returns the hyperbolic cosine of the argument.

Syntax

`cosh(z)`

Description

The cosh function calculates the hyperbolic cosine of z. z may be any numeric expression that evaluates to a real number or a complex number.

Hyperbolic cosine is defined as:  $\cosh(z) = \frac{1}{2}(e^z + e^{-z})$

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## **tanh function**

Returns the hyperbolic tangent of the argument.

Syntax

`tanh(z)`

Description

The tanh function calculates the hyperbolic tangent of z. z may be any numeric expression that evaluates to a real number or a complex number.

Hyperbolic tangent is defined as:  $\tanh(z) = \sinh(z)/\cosh(z)$

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## **asinh function**

Returns the inverse hyperbolic sine of the argument.

Syntax

`asinh(z)`

Description

The asinh function calculates the inverse hyperbolic sine of z. z may be any numeric expression that

# Label Format

---

evaluates to a real number or a complex number.  $\operatorname{asinh}$  is the reverse of  $\sinh$ , i.e.  $\operatorname{asinh}(\sinh(z)) = z$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## **acosh function**

Returns the inverse hyperbolic cosine of the argument.

Syntax

$\operatorname{acosh}(z)$

Description

The  $\operatorname{acosh}$  function calculates the inverse hyperbolic cosine of  $z$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number.  $\operatorname{acosh}$  is the reverse of  $\operatorname{cosh}$ , i.e.  $\operatorname{acosh}(\operatorname{cosh}(z)) = z$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## **atanh function**

Returns the inverse hyperbolic tangent of the argument.

Syntax

$\operatorname{atanh}(z)$

Description

The  $\operatorname{atanh}$  function calculates the inverse hyperbolic tangent of  $z$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number.  $\operatorname{atanh}$  is the reverse of  $\operatorname{tanh}$ , i.e.  $\operatorname{atanh}(\operatorname{tanh}(z)) = z$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## **csch function**

Returns the hyperbolic cosecant of the argument.

Syntax

$\operatorname{csch}(z)$

Description

The  $\operatorname{csch}$  function calculates the hyperbolic cosecant of  $z$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number.

Hyperbolic cosecant is defined as:  $\operatorname{csch}(z) = 1/\sinh(z) = 2/(e^z - e^{-z})$

# Label Format

---

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## sech function

Returns the hyperbolic secant of the argument.

Syntax

sech(z)

Description

The sech function calculates the hyperbolic secant of z. z may be any numeric expression that evaluates to a real number or a complex number.

Hyperbolic secant is defined as:  $\text{sech}(z) = 1/\cosh(z) = 2/(e^z + e^{-z})$

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## coth function

Returns the hyperbolic cotangent of the argument.

Syntax

coth(z)

Description

The coth function calculates the hyperbolic cotangent of z. z may be any numeric expression that evaluates to a real number or a complex number.

Hyperbolic cotangent is defined as:  $\text{coth}(z) = 1/\tanh(z) = \cosh(z)/\sinh(z) = (e^z + e^{-z})/(e^z - e^{-z})$

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## acsch function

Returns the inverse hyperbolic cosecant of the argument.

Syntax

acsch(z)

Description

The acsch function calculates the inverse hyperbolic cosecant of z. z may be any numeric expression that evaluates to a real number or a complex number. acsch is the reverse of csch, i.e.  $\text{acsch}(\text{csch}(z)) = z$ .

# Label Format

---

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## asech function

Returns the inverse hyperbolic secant of the argument.

Syntax

asech(z)

Description

The asech function calculates the inverse hyperbolic secant of z. z may be any numeric expression that evaluates to a real number or a complex number. asech is the reverse of sech, i.e.  $\text{asech}(\text{sech}(z)) = z$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## acoth function

Returns the inverse hyperbolic cotangent of the argument.

Syntax

acoth(z)

Description

The acoth function calculates the inverse hyperbolic cotangent of z. z may be any numeric expression that evaluates to a real number or a complex number. acoth is the reverse of coth, i.e.  $\text{acoth}(\text{coth}(z)) = z$ . For real numbers acoth is undefined in the interval  $[-1;1]$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Hyperbolic\\_function](http://en.wikipedia.org/wiki/Hyperbolic_function)]

---

## ***Power and logarithm***

### sqr function

Returns the square of the argument.

Syntax

sqr(z)

Description

The sqr function calculates the square of z, i.e. z raised to the power of 2. z may be any numeric expression that evaluates to a real number or a complex number.

# Label Format

---

## exp function

Returns e raised to the power of the argument.

### Syntax

`exp(z)`

### Description

The exp function is used to raise e, Euler's constant, to the power of z. This is the same as  $e^z$ . z may be any numeric expression that evaluates to a real number or a complex number.

### See also

Wikipedia [[http://en.wikipedia.org/wiki/Exponential\\_function](http://en.wikipedia.org/wiki/Exponential_function)]

---

## **sqrt function**

Returns the square root of the argument.

### Syntax

`sqrt(z)`

### Description

The sqrt function calculates the square root of z, i.e. z raised to the power of  $\frac{1}{2}$ . z may be any numeric expression that evaluates to a real number or a complex number. If the calculation is done with real numbers, the argument is only defined for  $z \geq 0$ .

### See also

Wikipedia [[http://en.wikipedia.org/wiki/Square\\_root](http://en.wikipedia.org/wiki/Square_root)]

---

## **root function**

Returns the nth root of the argument.

### Syntax

`root(n, z)`

### Description

The root function calculates the nth root of z. n and z may be any numeric expression that evaluates to a real number or a complex number. If the calculation is done with real numbers, the argument is only defined for  $z \geq 0$ .

### Remarks

When the calculation is done with real numbers, the function is only defined for  $z < 0$  if n is an odd integer. For calculations with complex numbers, root is defined for the whole complex plane except at the pole  $n=0$ .

# Label Format

---

Notice that for calculations with complex numbers the result will always have an imaginary part when  $z < 0$  even though the result is real when calculations are done with real numbers and  $n$  is an odd integer.

Example

Instead of  $x^{(1/3)}$ , you can use `root(3, x)`.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Nth\\_root](http://en.wikipedia.org/wiki/Nth_root)]

---

## In function

Returns the natural logarithm of the argument.

Syntax

`ln(z)`

Description

The `ln` function calculates the logarithm of  $z$  with base  $e$ , which is Euler's constant. `ln(z)` is commonly known as the natural logarithm.  $z$  may be any numeric expression that evaluates to a real number or a complex number. If the calculation is done with real numbers, the argument is only defined for  $z > 0$ . When calculating with complex numbers,  $z$  is defined for all numbers except  $z = 0$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Natural\\_logarithm](http://en.wikipedia.org/wiki/Natural_logarithm)]

---

## log function

Returns the base 10 logarithm of the argument.

Syntax

`log(z)`

Description

The `log` function calculates the logarithm of  $z$  with base 10.  $z$  may be any numeric expression that evaluates to a real number or a complex number. If the calculation is done with real numbers, the argument is only defined for  $z > 0$ . When calculating with complex numbers,  $z$  is defined for all numbers except  $z = 0$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Common\\_logarithm](http://en.wikipedia.org/wiki/Common_logarithm)]

---

## logb function

Returns the base  $n$  logarithm of the argument.

Syntax

`logb(z, n)`

# Label Format

---

## Description

The `logb` function calculates the logarithm of  $z$  with base  $n$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number. If the calculation is done with real numbers, the argument is only defined for  $z > 0$ . When calculating with complex numbers,  $z$  is defined for all numbers except  $z = 0$ .  $n$  must evaluate to a positive real number.

See also

Wikipedia [<http://en.wikipedia.org/wiki/Logarithm>]

---

## Complex

### abs function

Returns the absolute value of the argument.

Syntax

`abs(z)`

## Description

The `abs` function returns the absolute or numeric value of  $z$ , commonly written as  $|z|$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number. `abs(z)` always returns a positive real value.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Absolute\\_value](http://en.wikipedia.org/wiki/Absolute_value)]

---

### arg function

Returns the argument of the parameter.

Syntax

`arg(z)`

## Description

The `arg` function returns the argument or angle of  $z$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number. `arg(z)` always returns a real number. The result may be in radians or degrees depending on the current settings. The angle is always between  $-p$  and  $p$ . If  $z$  is a real number,

`arg(z)`

is 0 for positive numbers and  $p$  for negative numbers. `arg(0)` is undefined.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Arg\\_\(mathematics\)](http://en.wikipedia.org/wiki/Arg_(mathematics))]

---

# Label Format

---

## conj function

Returns the conjugate of the argument.

Syntax

conj(z)

Description

The conj function returns the conjugate of z. z may be any numeric expression that evaluates to a real number or a complex number. The function is defined as:  $\text{conj}(z) = \text{re}(z) - i*\text{im}(z)$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Complex\\_conjugation](http://en.wikipedia.org/wiki/Complex_conjugation)]

---

## re function

Returns the real part of the argument.

Syntax

re(z)

Description

The re function returns the real part of z. z may be any numeric expression that evaluates to a real number or a complex number.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Real\\_part](http://en.wikipedia.org/wiki/Real_part)]

---

## im function

Returns the imaginary part of the argument.

Syntax

im(z)

Description

The im function returns the imaginary part of z. z may be any numeric expression that evaluates to a real number or a complex number.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Imaginary\\_part](http://en.wikipedia.org/wiki/Imaginary_part)]

---

## ***Rounding***

# Label Format

---

## trunc function

Removes the fractional part of the argument.

Syntax

`trunc(z)`

Description

The trunc function returns the integer part of  $z$ . The function removes the decimal part of  $z$ , i.e. rounds against zero.  $z$  may be any numeric expression that evaluates to a real number or a complex number. If  $z$  is a complex number, the function returns  $\text{trunc}(\text{re}(z)) + \text{trunc}(\text{im}(z))i$ .

See also

Wikipedia [<http://en.wikipedia.org/wiki/Truncate>]

---

## fract function

Returns the fractional part of the argument.

Syntax

`fract(z)`

Description

The fract function returns the fractional part of  $z$ . The function removes the integer part of  $z$ , i.e.  $\text{fract}(z) = z - \text{trunc}(z)$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number. If  $z$  is a complex number, the function returns  $\text{fract}(\text{re}(z)) + \text{fract}(\text{im}(z))i$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Floor\\_and\\_ceiling\\_functions#Fractional\\_part](http://en.wikipedia.org/wiki/Floor_and_ceiling_functions#Fractional_part)]

---

## ceil function

Rounds the argument up.

Syntax

`ceil(z)`

Description

The ceil function finds the smallest integer not less than  $z$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number. If  $z$  is a complex number, the function returns  $\text{ceil}(\text{re}(z)) + \text{ceil}(\text{im}(z))i$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Floor\\_and\\_ceiling\\_functions](http://en.wikipedia.org/wiki/Floor_and_ceiling_functions)]

---

# Label Format

---

## floor function

Rounds the argument down.

Syntax

$\text{floor}(z)$

Description

The floor function, which is also called the greatest integer function, gives the largest integer not greater than  $z$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number. If  $z$  is a complex number, the function returns  $\text{floor}(\text{re}(z)) + \text{floor}(\text{im}(z))i$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Floor\\_and\\_ceiling\\_functions](http://en.wikipedia.org/wiki/Floor_and_ceiling_functions)]

---

## round function

Rounds a number to the specified number of decimals.

Syntax

$\text{round}(z,n)$

Description

The round function rounds  $z$  to the number of decimals given by  $n$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number. If  $z$  is a complex number, the function returns  $\text{round}(\text{re}(z),n) + \text{round}(\text{im}(z),n)i$ .  $n$  may be any numeric expression that evaluates to an integer. If  $n < 0$ ,  $z$  is rounded to  $n$  places to the left of the decimal point.

Examples

$\text{round}(412.4572,3) = 412.457$

$\text{round}(412.4572,2) = 412.46$

$\text{round}(412.4572,1) = 412.5$

$\text{round}(412.4572,0) = 412$

$\text{round}(412.4572,-2) = 400$

See also

Wikipedia [<http://en.wikipedia.org/wiki/Rounding>]

---

## *Piecewise*

### sign function

Returns the sign of the argument.

Syntax

$\text{sign}(z)$

# Label Format

---

## Description

The sign function, which is also called signum, returns the sign of  $z$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number. When  $z$  is a real number,  $\text{sign}(z)$  returns 1 for  $z > 0$  and -1 for  $z < 0$ .  $\text{sign}(z)$  returns 0 for  $z = 0$ . When  $z$  evaluates to a complex number,  $\text{sign}(z)$  returns  $z/\text{abs}(z)$ .

## See also

Wikipedia [[http://en.wikipedia.org/wiki/Sign\\_function](http://en.wikipedia.org/wiki/Sign_function)]

---

## u function

The unit step function.

## Syntax

$u(z)$

## Description

$u(z)$  is commonly known as the unit step function.  $z$  may be any numeric expression that evaluates to a real number. The function is undefined when  $z$  has an imaginary part.  $u(z)$  returns 1 for  $z \geq 0$  and 0 for  $z < 0$ .

## See also

Wikipedia [[http://en.wikipedia.org/wiki/Unit\\_step#Discrete\\_form](http://en.wikipedia.org/wiki/Unit_step#Discrete_form)]

---

## min function

Finds and returns the minimum of the values passed as arguments.

## Syntax

$\text{min}(A, B, \dots)$

## Description

The min function returns the minimum value of its arguments. min can take any number of arguments not less than 2. The arguments may be any numeric expressions that evaluate to real numbers or complex numbers. If the arguments are complex numbers, the function returns  $\text{min}(\text{re}(A), \text{re}(B), \dots) + \text{min}(\text{im}(A), \text{im}(B), \dots)i$ .

---

## max function

Finds and returns the maximum of the values passed as arguments.

## Syntax

$\text{max}(A, B, \dots)$

## Description

The max function returns the maximum value of its arguments. max can take any number of arguments

# Label Format

---

not less than 2. The arguments may be any numeric expressions that evaluate to real numbers or complex numbers. If the arguments are complex numbers, the function returns  $\max(\text{re}(A), \text{re}(B), \dots) + \max(\text{im}(A), \text{im}(B), \dots)i$ .

---

## range function

Returns the second argument if it is in the range between the first argument and the third argument.

Syntax

`range(A,z,B)`

Description

The range function returns  $z$ , if  $z$  is greater than  $A$  and less than  $B$ . If  $z < A$  then  $A$  is returned. If  $z > B$  then  $B$  is returned. The arguments may be any numeric expressions that evaluate to real numbers or complex numbers. The function has the same effect as  $\max(A, \min(z, B))$ .

---

## if function

Evaluates one or more conditions and returns a different result based on them.

Syntax

`if(cond1, f1, cond2, f2, ... , condn, fn [,fz])`

Description

The if function evaluates  $\text{cond1}$  and if it is different from 0 then  $f1$  is evaluated and returned. Else  $\text{cond2}$  is evaluated and if it is different from 0 then  $f2$  is returned and so forth. If none of the conditions are true  $fz$  is returned.  $fz$  is optional and if not specified if returns an error if none of the conditions are true. The arguments may be any numeric expressions that evaluate to real numbers or complex numbers.

---

## Special

### integrate function

Returns an approximation for the numerical integral of the given expression over the given range.

Syntax

`integrate(f,var,a,b)`

Description

The integrate function returns an approximation for the numerical integral of  $f$  with the variable  $\text{var}$

# Label Format

---

from a to b. This is mathematically written as:

$$\int_a^b f(x) dx$$

This integral is the same as the area between the function f and the x-axis from a to b where the area under the axis is counted negative. f may be any function with the variable indicated as the second argument var. a and b may be any numeric expressions that evaluate to real numbers or they can be -INF or INF to indicate negative or positive infinity. integrate does not calculate the integral exactly. Instead the calculation is done using the Gauss-Kronrod 21-point integration rule adaptively to an estimated relative error less than 10<sup>-3</sup>.

Examples

f(x)=integrate(t^2-7t+1, t, -3, 15) will integrate f(t)=t^2-7t+1 from -3 to 15 and evaluate to 396. More useful

is f(x)=integrate(s\*sin(s), s, 0, x). This will plot the integral of f(s)=s\*sin(s) from 0 to x, which is the same as the definite integral of f(x)=x\*sin(x).

See also

Wikipedia [<http://en.wikipedia.org/wiki/Integral>]

---

## sum function

Returns the summation of an expression evaluated over a range of integers.

Syntax

sum(f,var,a,b)

Description

The sum function returns the summation of f where var is evaluated for all integers from a to b. This is mathematically written as:

$$\sum_{x=a}^b f(x)$$

f may be any function with the variable indicated as the second argument var. a and b may be any numeric expressions that evaluate to integers.

See also

Wikipedia [<http://en.wikipedia.org/wiki/Summation>]

---

## product function

Returns the product of an expression evaluated over a range of integers.

Syntax

# Label Format

---

product(f,var,a,b)

## Description

The product function returns the product of f where var is evaluated for all integers from a to b. This is mathematically written as:

$$\prod_{x=a}^b f(x)$$

f may be any function with the variable indicated as the second argument var. a and b may be any numeric expressions that evaluate to integers.

Wikipedia [[http://en.wikipedia.org/wiki/Multiplication#Capital\\_pi\\_notation](http://en.wikipedia.org/wiki/Multiplication#Capital_pi_notation)]

---

## fact function

Returns the factorial of the argument.

Syntax

fact(n)

## Description

The fact function returns the factorial of n, commonly written as n!. n may be any numeric expression that evaluates to a positive integer. The function is defined as fact(n)=n(n-1)(n-2)...1, and relates to the gamma function as fact(n)=gamma(n+1).

See also

Wikipedia [<http://en.wikipedia.org/wiki/Factorial>]

---

## gamma function

Returns the value of the Euler gamma function of the argument.

Syntax

gamma(z)

## Description

The gamma function returns the result of the Euler gamma function of z, commonly written as G(z). z may be any numeric expression that evaluates to a real number or a complex number. The gamma function relates

to the factorial function as fact(n)=gamma(n+1). The mathematical definition of the gamma function is:

$$\Gamma(z) = \int_0^{\infty} t^{z-1} e^{-t} dt$$

# Label Format

---

This cannot be calculated precisely, so Graph is using the Lanczos approximation to calculate the gamma function.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Gamma\\_function](http://en.wikipedia.org/wiki/Gamma_function)]

---

## beta function

Returns the value of the Euler beta function evaluated for the arguments.

Syntax

beta(m, n)

Description

The beta function returns the result of the Euler beta function evaluated for m and n. m and n may be any numeric expressions that evaluate to real numbers or complex numbers. The beta function relates to the gamma function as  $\text{beta}(m, n) = \text{gamma}(m) * \text{gamma}(n) / \text{gamma}(m+n)$ .

See also

Wikipedia [[http://en.wikipedia.org/wiki/Beta\\_function](http://en.wikipedia.org/wiki/Beta_function)]

---

## W function

Returns the value of the Lambert W-function evaluated for the argument.

Syntax

W(z)

Description

The W function returns the result of the Lambert W-function, also known as the omega function, evaluated for

z. z may be any numeric expression that evaluates to a real number or a complex number. The inverse of the

W function is given by  $f(W)=W*e^W$ .

Remarks

For real values of z when  $z < -1/e$ , the W function will evaluate to values with an imaginary part.

See also

Wikipedia [[http://en.wikipedia.org/wiki/Lambert\\_w\\_function](http://en.wikipedia.org/wiki/Lambert_w_function)]

---

## zeta function

Returns the value of the Riemann Zeta function evaluated for the argument.

# Label Format

---

## Syntax

zeta(z)

## Description

The zeta function returns the result of the Riemann Zeta function, commonly written as  $\zeta(s)$ .  $z$  may be any numeric expression that evaluates to a real number or a complex number.

## Remarks

The zeta function is defined for the whole complex plane except for the pole at  $z=1$ .

## See also

Wikipedia [[http://en.wikipedia.org/wiki/Riemann\\_zeta\\_function](http://en.wikipedia.org/wiki/Riemann_zeta_function)]

---

## mod function

Returns the remainder of the first argument divided by the second argument.

## Syntax

mod(m,n)

## Description

Calculates  $m$  modulo  $n$ , the remainder of  $m/n$ .  $\text{mod}$  calculates the remainder  $f$ , where  $m = a*n + f$  for some integer  $a$ . The sign of  $f$  is always the same as the sign of  $n$ . When  $n=0$ ,  $\text{mod}$  returns 0.  $m$  and  $n$  may be any numeric expressions that evaluate to real numbers.

## See also

Wikipedia [[http://en.wikipedia.org/wiki/Modular\\_arithmetic](http://en.wikipedia.org/wiki/Modular_arithmetic)]

---

## dnorm function

Returns the normal distribution of the first argument with optional mean value and standard deviation.

## Syntax

dnorm(x, [ $\mu$ , $s$ ])

## Description

The  $\text{dnorm}$  function is the probability density of the normal distribution, also called Gaussian distribution.  $x$  is the variate, also known as the random variable,  $\mu$  is the mean value and  $s$  is the standard deviation.  $\mu$  and  $s$  are optional and if left out the standard normal distribution is used where  $\mu=0$  and  $s=1$ .  $x$ ,  $\mu$  and  $s$  may be any numeric expressions that evaluate to real numbers where  $s > 0$ . The normal distribution is defined as:

$$\text{dnorm}(x, \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

# Label Format

---
